During the last five years mesospheric gravity wave activities have been observed using an all-sky imager at Sao Joao do Cariri 7 4S 36 5W Brazil Among these waves particularly interesting phenomenon is mesospheric front whose origin and physics are not well known The mesospheric front is a well defined leading edge of the airglow emission layer that is spatially extended and pronounced in It is suggested that the development of these fronts is strongly associated with the MLT thermal structure In the present paper we will use kinetic temperature profile data obtained by TIMED SABER satellite to discuss the atmospheric background conditions where the mesospheric fronts propagate
